REC_Python_Week 4_CY

Attempt : 1
Total Mark : 40
Marks Obtained : 40

Section 1 : Coding

1. Problem Statement

Develop a text analysis tool that needs to count the occurrences of a specific substring within a given text string.

Write a function `count_substrings(text, substring)` that takes two inputs: the text string and the substring to be counted. The function should count how many times the substring appears in the text string and return the count.

Function Signature: `count_substrings(text, substring)`

Input Format

The first line of the input consists of a string representing the text.

The second line consists of a string representing the substring.

Output Format

The output should display a single line of output containing the count of occurrences of the substring in the text string.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: programming is fun and programming is cool
programming

Output: The substring 'programming' appears 2 times in the text.

Answer

```
# You are using Python
n=input()
n1=input()
t=n.count(n1)
print(f"The substring '{n1}' appears {t} times in the text.")
```

Status : Correct

Marks : 10/10

2. Problem Statement

Arjun is working on a mathematical tool to manipulate lists of numbers. He needs a program that reads a list of integers and generates two lists: one containing the squares of the input numbers, and another containing the cubes. Arjun wants to use lambda functions for both tasks.

Write a program that computes the square and cube of each number in the input list using lambda functions.

Input Format

The input consists of a single line of space-separated integers representing the list of input numbers.

Output Format

The first line contains a list of the squared values of the input numbers.

The second line contains a list of the cubed values of the input numbers.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 1 2 3

Output: [1, 4, 9]

[1, 8, 27]

Answer

```
# You are using Python
n=list(map(int,input().split()))
s=list(map(lambda x:x**2,n))
s1=list(map(lambda x1:x1**3,n))
print(s)
print(s1)
```

Status : Correct

Marks : 10/10

3. Problem Statement

Amrita is developing a password strength checker for her website. She wants the checker to consider the length and the diversity of characters used in the password. A strong password should be long and include a mix of character types: uppercase, lowercase, digits, and special symbols.

She also wants the feedback to be user-friendly, so she wants to include the actual password in the output. Help Amrita finish this password checker using Python's built-in string methods.

Character Types Considered:

Lowercase letters (a-z) Uppercase letters (A-Z) Digits (0-9) Special characters (from string.punctuation, e.g. @, !, #, \$)

Input Format

The input consists of a single string representing the user's password.

Output Format

The program prints the strength of the password in this format:

If the password length < 6 characters or fewer than 2 of the 4 character types, the output prints "<password> is Weak"

If password length ≥ 6 and at least 2 different character types, the output prints "<password> is Moderate"

If Password length ≥ 10 and all 4 character types present, the output prints "<password> is Strong"

Refer to the sample output for formatting specifications.

Sample Test Case

Input: password123

Output: password123 is Moderate

Answer

You are using Python

```
n=input()
```

```
s=len(n)
```

```
l=0
```

```
u=0
```

```
d=0
```

```
s1=0
```

```
for i in n:
```

```
    if(i.islower()):
```

```
        l=1
```

```
    elif(i.isupper()):
```

```
        u=1
```

```
    elif(i.isdigit()):
```

```
        d=1
```

```
    else:
```

```
        s1=1
```

```
t=l+u+d+s1
#print(t)
# print(s)
if(s>=10 and t==4):
    print(f"{n} is strong")
elif(s>=6 and t>=2):
    print(f"{n} is Moderate")
else:
    print(f"{n} is Weak")
```

Status : Correct

Marks : 10/10

4. Problem Statement

Meena is analyzing a list of integers and needs to count how many numbers in the list are even and how many are odd. She decides to use lambda functions to filter the even and odd numbers from the list.

Write a program that takes a list of integers, counts the number of even and odd numbers using lambda functions, and prints the results.

Input Format

The first line contains an integer n, representing the number of integers in the list.

The second line contains n space-separated integers.

Output Format

The first line of output prints an integer representing the count of even numbers.

The second line of output prints an integer representing the count of odd numbers.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 7

12 34 56 78 98 65 23

Output: 5

2

Answer

You are using Python

```
n=int(input())
```

```
n1=list(map(int,input().split()))
```

```
s=len(list(filter(lambda x:x%2==0,n1)))
```

```
s1=len(list(filter(lambda x1:x1%2!=0,n1)))
```

```
print(s)
```

```
print(s1)
```

Status : Correct
